3.1

- You are provided with a gridworld environment where an agent can move up, down, left, or right. The agent starts each episode at a specific location and receives rewards based on the environment's layout.
- Implement the **Greedy** and **Epsilon-Greedy** policies in the functions **GreedyPolicy** and **EpsilonGreedyPolicy** respectively.
- Implement the **Q-learning** algorithm in the function **q_learning**, which will update the **Q-table** based on the agent's actions and rewards.
- Run 10000 episodes of Q-learning with $\epsilon = 0.5$, $\beta = 0$, $\alpha = 0.1$, and $\gamma = 0.95$. Visualize the results at various stages (after 10, 100, 1000, and 10000 episodes).
- Answer the following questions:
 - 1. What has the agent learned after the first 10 episodes?
 - 2. Is the final greedy policy (after 10000 episodes) optimal for all states? Why or why not?
 - 3. Do the learned values in the Q-table reflect the existence of multiple paths to the positive reward?

Q-table after 1000 iterations (epsilon = 0.5, alpha = 0.1 gamma = 0.95, beta = 0)

- Q: What has the agent learned after the first 10 episodes? A: To not enter(4, 3)
- Q: Is the final greedy policy (after 10000 episodes) optimal for all states, i.e. not only for the initial state? Why / Why not? A: No. For example, the action policy for state (5, 3) is to go left, but the optimal action is right. This is due to the agent not having had the chance of exploring this state enough times.
- Q: Do the learned values in the Q-table reflect the fact that there are multiple paths (above and below the negative rewards) to get to the positive reward? If not, what could be done to make it happen? A: No, it always tries to go below. We could either enforce a greater epsilon, or change start_state to be further up (e.g (1, 5))

3.3

Environment B: - Investigate the effects of different values of ϵ and γ by running 30000 episodes of Q-learning with various configurations.

Q: Investigate how the β parameter affects the learned policy. A: Having a higher β worsen the model. This is due to it becoming more difficult for the agent to understand the task. Choosing an optimal action can lead to a negative reward.

3.6

Environment D: - Evaluate the agent's performance after training on eight goal positions and validating on the remaining eight. Answer questions regarding the learned policy's effectiveness.

 $https://github.com/STIMALiU/AdvMLCourse/blob/master/ReinforcementLearning/RL_Lab2_Colab. ipynb$

- Q: Has the agent learned a good policy? Why / Why not? A: Yes, it is performing well finding the optimal policy. It seems to have learnt a policy taking to account the goal target.
- Q: Could you have used the Q-learning algorithm to solve this task? A: In theory yes, if it got to explore all combinations of states and goals, but Q-learning does not generalize.

2.7

Environment E: - Analyze the agent's policy when trained on goals from the top row and validated on goals from the lower rows. Compare the results with Environment D.

In this task, the goals for training are all from the top row of the grid. The validation goals are three positions from the rows below.

Q: Has the agent learned a good policy? Why / Why not? A: No, the agent tends to want to move upward, since that's what had the best return during training.

Q: If the results obtained for environments D and E differ, explain why. A: The agent in E is only trained on goals to the top, causing its policy to perform bad for goals at the bottom.
